

Hej!

How many talks have you  
heard about IPv6?

30?

100?

1000?

Had enough yet?

I have!

This is **not** a talk about  
IPv6.

This is a talk about our  
industry

and what is happening to  
the Internet

and what we might want  
to do about it!

# Where have all the ISPs Gone?

Geoff Huston

APNIC

The Internet has often been portrayed as the “poster child” for deregulation in the telecommunications sector.

The rapid proliferation of new services, the creation of new markets, and the intense level of competition in every aspect of the Internet is seen as a successful outcome of this policy of deliberate disengagement by the regulator.

But is this true today?

Do we still see intense competition in this industry? Is there still strong impetus for innovation and entrepreneurial enterprise?

Or is this industry lapsing back into a mode of local monopolies, vertical bundling and strong resistance to further change and innovation?

# How “Balanced” is this industry?

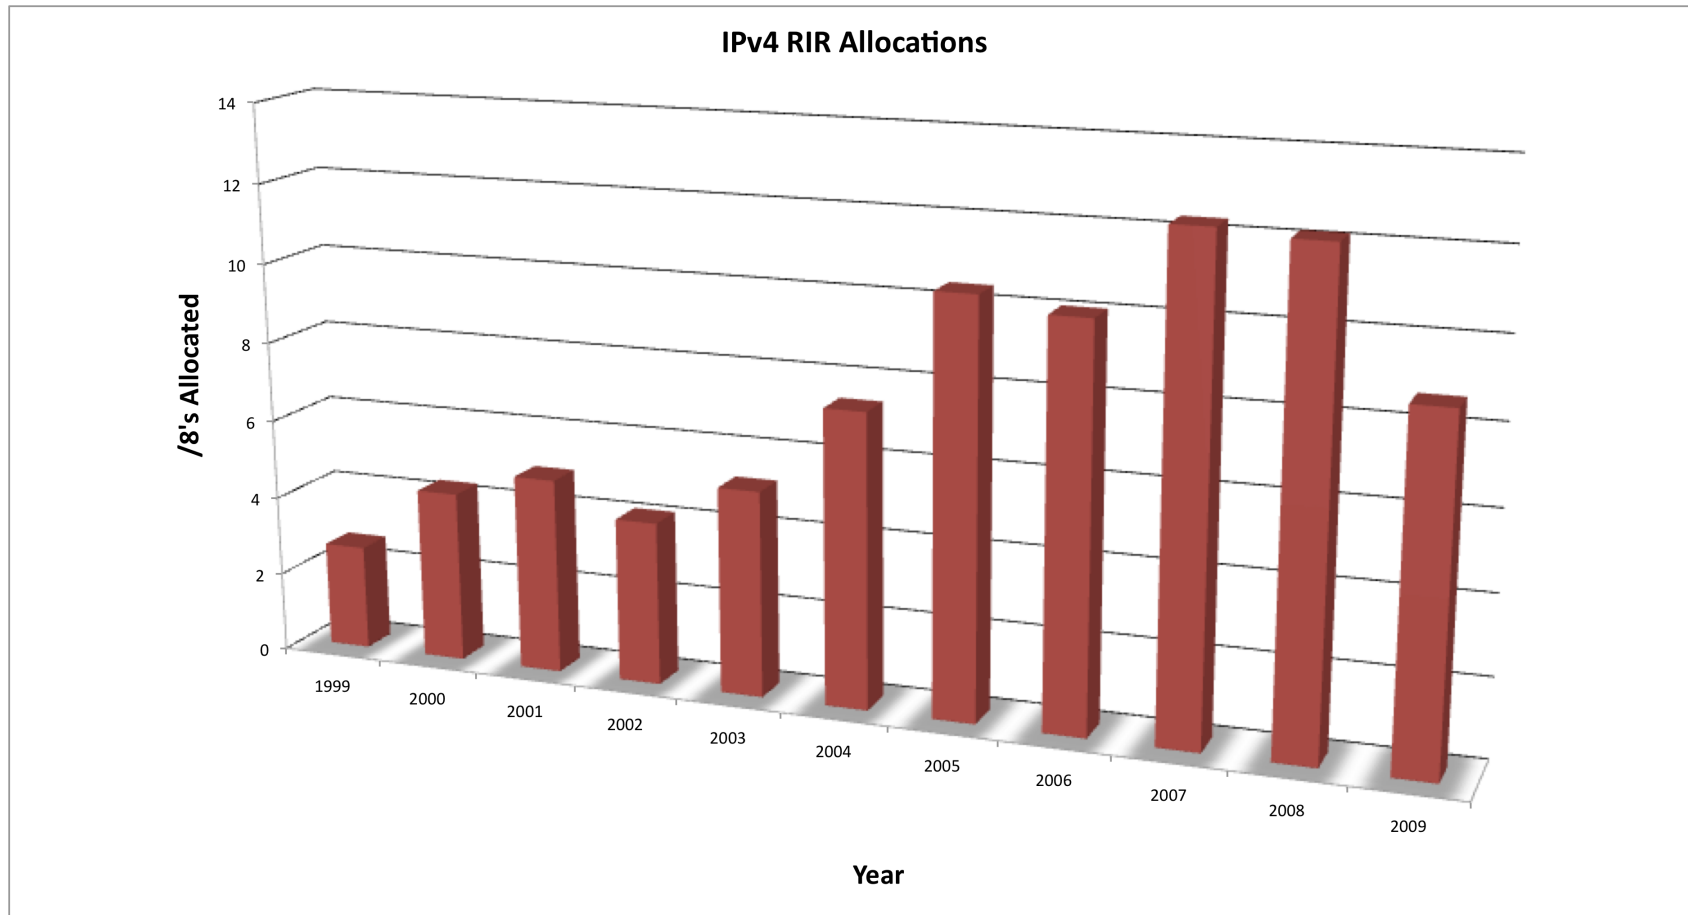

A diverse connection  
of large and small  
ISP enterprises

OR

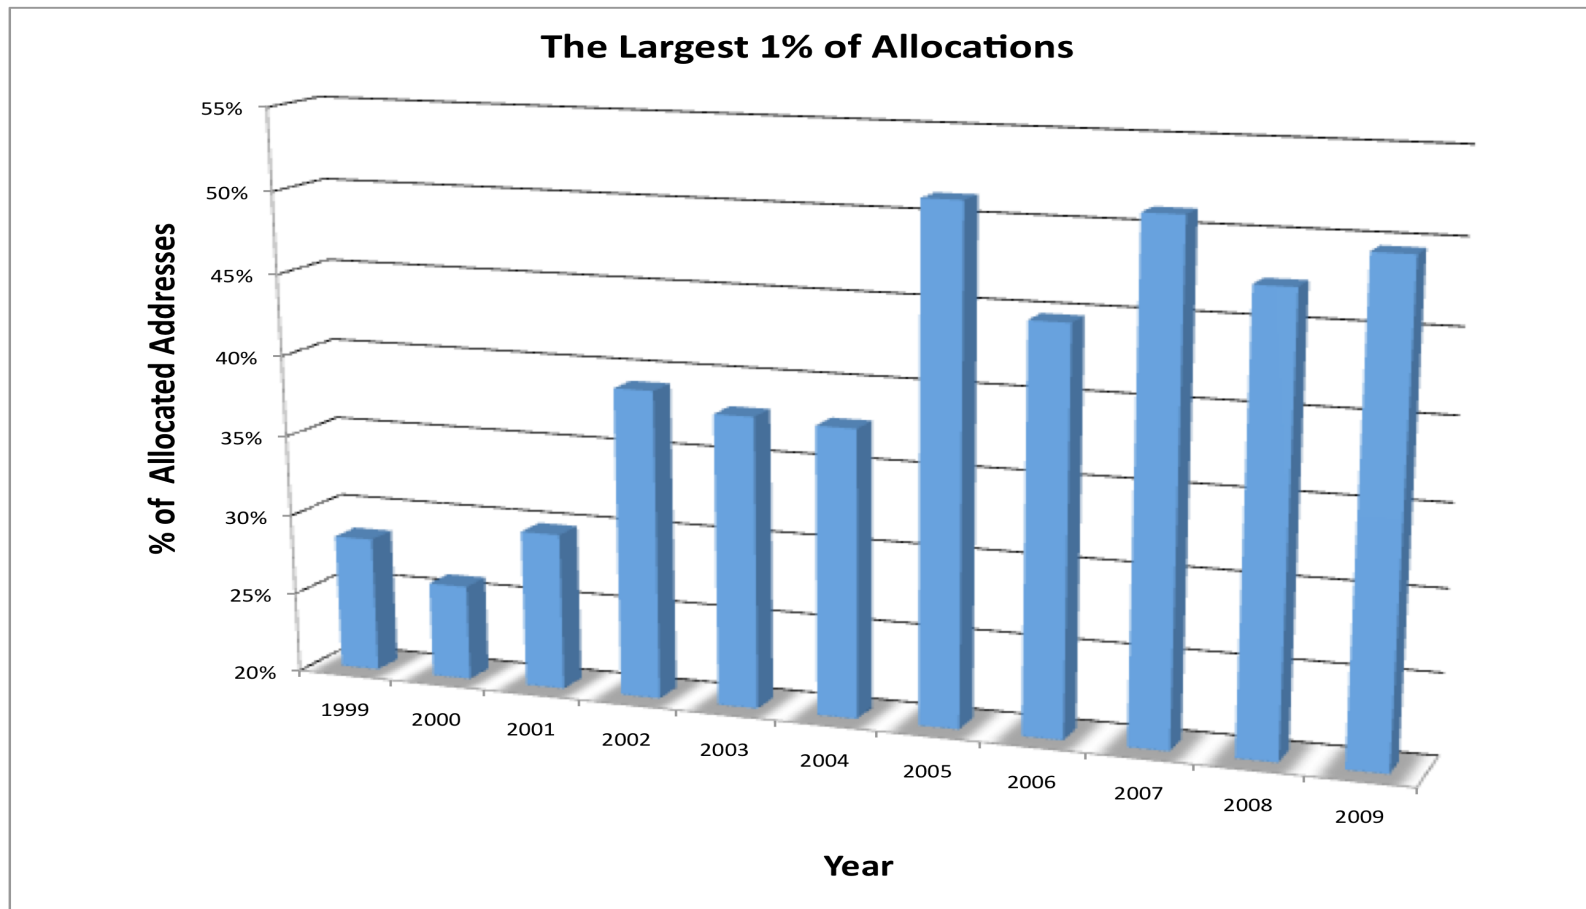

A small number of very  
large enterprises and  
some very small  
independent players

# How “Balanced” is this Industry?

What can IPv4 address allocations tell us about this industry?

# How “Balanced” is this Industry?

Massive consolidation in this industry appears to have been in place since 2005

# How “Balanced” is this Industry?

Massive consolidation in this industry appears to have been in place since 2005

# How did we get here?

# How did we get here?

# The Rise of the Monopoly Telco

By the early 1980's the telco sector had reached its glorious peak

# The Rise of the Monopoly Telco

Some decades of careful planning and construction had resulted in:

- a fully funded and comprehensive infrastructure
- massive margins
- an interlocking structure of monopolies
- control over offered services
- control over technology
- control over the regulatory sector
- control over the user

# Sowing the Seeds of Decline

At the same time there were pressures being placed on these lucrative telco monopolies:

- the shift to digital switching technologies inside the telco network had reduced cost, but prices remained high
- prevailing high operating margins created strong investment pressure to open this activity to private sector investment
- public sector reluctance to continue to commit more public funds to capital investment in communications infrastructure

# Deregulation of the Telco

- Progressive wave of deregulation and privatization of the telco sector in the late 80's
  - unbundling monopoly control
  - private sector investment
  - competitive carriers
  - competitive services
  - competitive suppliers

# The Reaction to Deregulation

- Initial wave of competitive full service telcos
  - competition in full service telephony proved expensive and inefficient

# The Reaction to Deregulation

- A second wave of specialized competition was directed at areas of high return or high vulnerability
- Unbundling the telco monopoly by competition in:
  - mobile telephony
  - long distance telephone
  - specialized data services

# The Rise of the Internet

- Entrance of the ISP as a Value-Added Data Service Provider
  - leased line capacity from the telco
  - use local phone network as the last mile access
  - add modems and IP routers
  - and connect up all those shiny new PCs that were entering the consumer electronics market

# The Rise and Rise of the Internet

- New markets to complement these basic access IP providers:
  - content providers
  - portals and content aggregators
  - indexing and search engines
  - advertising
  - social networks
- unbundling the original “vertically integrated full service model” to create an entirely new sets of industry players

# The Cyberspace Tussle: “old” Telco vs the “new” Internet

# The Golden Age of the ISP

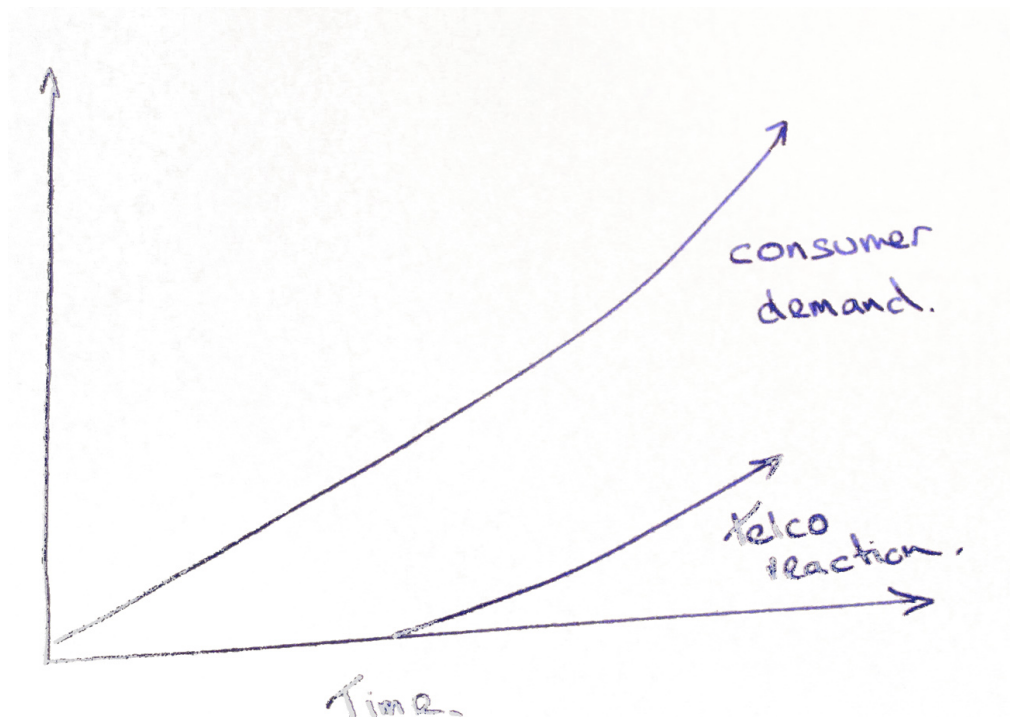

- The market for Internet services was moving faster than the telco's could react

“The pace of new problems appearing is much faster than our ability to solve any of them”

*Telco Exec, Bell Canada, 1996*

# The Golden Age of the ISP

The market for Internet services was moving faster than the telco's could react

# The Golden Age of the ISP

Creating a unique market opportunity for entrepreneurial capital

# The Golden ISP Age

- The late 90's produced thousands of ISPs that were leveraged off cheap dialup access:
  - Cost of calls: \$0
  - Cost of infrastructure per customer: \$200 or so
  - Value of the customer: \$2000
  - Net Return: 1000% What a business!

# But...

- Customers wanted higher speeds
- ISPs were not positioned to undertake massive capital investment in infrastructure
- And the emerging economies of scale said “Get big or get bought”

# The last 6 years

- Telcos shift to DSL and 3G access for IP
  - eliminate modem loads on the PSTN
  - eliminate dial-based overlay access from competitors
  - shift to an access technologies that required relatively small capital investment on the part of the telco with its existing installed infrastructure, but cut out the under-capitalized ISP competitors

# Today

- Economies of scale dominate this industry
- Large-scale providers are reasserting their dominance over the IP market

# FTTH – A New Access Monopoly?

FTTH requires relatively high level of capital investment

- investment risks are reduced if competitive access is eliminated
- returns are improved if vertical service bundling can be put in place to allow structural cross-subsidization

# Public Risks

- Escalation of consumer prices
- Barriers to competitive access
- Barriers to technology and service innovation
- Rebuilding monopoly control over technology and services

# What about the “Open Architecture” of IP?

- Scarcity of addresses in IPv4 is helping the push to vertical service integration
  - If you are an access provider, and what you want is to regain control of the entire IP service environment then:
    - NATs can be good
    - Application Level gateways are even better!
    - IPv6 is not good!
- IPv6 reopens the network to competitive overlays and overlay services, and potentially pushes back the access provider to a commodity packet pushing role

# What About IPv6?

## The Plan

# Where are we?

- We seem to be back to a familiar situation
  - a small number of players with a large footprint over the market
  - rising barriers to competitive access by new market entrants
  - increasing aspects of control over delivered services – “vertical integration” from telco ISPs is back in vogue in many markets
  - increasing resistance by the incumbents to any change that could open up the market to innovation and competition

# Where are we?

The enterprises that dominate today's access and carriage activities in the Internet have no direct interest in making investments in a new protocol such as IPv6 that simply leaves the gate open for the continued provision of edge-to-edge overlay services that capture the Internet's major revenue streams

# Market Theory

Is this IPv6 transition an instance of a *Market Failure?*

Individual self-interest on the part of the small number of large providers is not being directed to IPv6 adoption

The barriers to market entry prevent others from entering the market to provide IPv6 services

*Nothing happens!*

# And Where To?

- How important is it to operate a capable and open infrastructure for the public communications sector?
- What is the appropriate balance between public sector direction and private sector activity?
- Where is the true value in communication: the carriage of the packet or its content?
- What do we want from the Internet?

# A New Zealand Approach

“The minister for communications and information technology does not believe that regulatory intervention is appropriate. Adoption of IPv6 needs to be lead by the private sector. The private sector must recognise that adopting IPv6 is in their own best interests to protect their investment in online capabilities into the future. Issues of advantages and disadvantages, costs, risks, timing, methodology etc, have to be for each enterprise to assess for itself.”

Statement by the New Zealand Minister for Communications  
24 August 2009

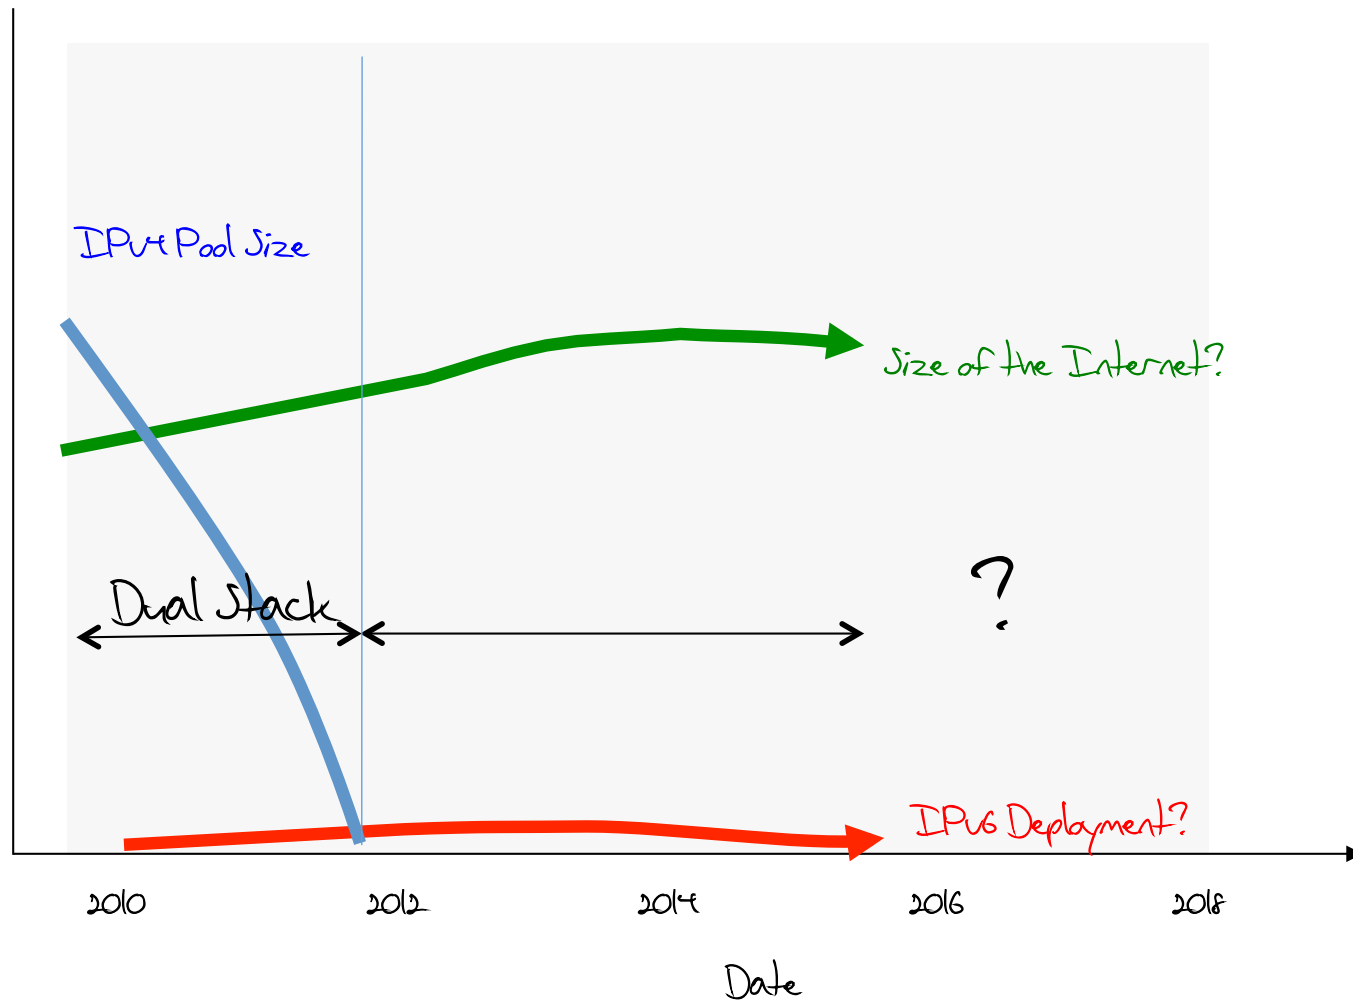

# An Australian Approach

- The “National Broadband Network”
  - \$ 43 billion of public funds (\$2000 per capita)
  - FTTH for 90% of the continent
  - “neutral” national access network for data and voice
  - no more copper loop
- De-Fanging the telco
  - structural separation by legislation into retail and wholesale components
  - limits on 3G spectrum and content ownership

# Striking a Balance

- There are very few industries where the private sector is entirely capable of looking after the public interest
- We now need robust active public regulatory frameworks that can support vibrant industry competition, fundamental innovation and maintain the enduring public value of our Internet

# And if we get it wrong...

Actually, I lied ...

I mentioned IPv6, didn't I!

Ursäkta!

Thank You!
